Waves and Diffusions

1.1 The wave equation

We already know the wave equation ($c > 0$):

$$u_{tt} - c^2 u_{xx} = 0, \quad -\infty < x < \infty,$$

and the general solution is of the form

$$u(x, t) = f(x + ct) + g(x - ct).$$

With initial conditions imposed, we have the IVP

$$u_{tt} - c^2 u_{xx} = 0, \quad \begin{cases} u(x, 0) = \phi(x), \\ u_t(x, 0) = \psi(x). \end{cases}$$

The solution to IVP is then

$$u(x) = \frac{1}{2}[\phi(x + ct) + \phi(x - ct)] + \frac{1}{2c} \int_{x-ct}^{x+ct} \psi(s) ds.$$

To interpret the integral, we can let $\psi(x) = \mu'(x)$, then the integral becomes

$$\int_{x-ct}^{x+ct} \psi(s) ds = \mu(x + ct) - \mu(x - ct).$$

1.2 Conservation laws

Given a wave equation, we multiply by u_t :

$$\begin{aligned} u_t u_{tt} - c^2 u_t u_{xx} &= 0 \\ \frac{\partial}{\partial t} \left(\frac{1}{2} u_t^2 \right) - c^2 \left[\frac{\partial}{\partial x} (u_t u_x) - u_{tx} u_x \right] &= 0 \\ \frac{\partial}{\partial t} \left(\frac{1}{2} u_t^2 + \frac{c^2}{2} u_x^2 \right) - \frac{\partial}{\partial x} (c^2 u_t u_x) &= 0 \end{aligned}$$

Then the conservation law states that

$$\frac{\partial R}{\partial t} + \frac{\partial F}{\partial x} = 0,$$

where $R \in (-\infty, +\infty)$, and $F \rightarrow 0$ with $x \rightarrow \pm\infty$.

1.3 The Diffusion Equation & Maximum principle

The diffusion equation is given by

$$u_t = ku_{xx}, \quad -\infty < x < \infty$$

with diffusion constant $k > 0$.

We define

$$R = (a, b) \times (0, \infty)$$

$$R_T = (a, b) \times (0, T]$$

$$\overline{R_T} = [a, b] \times [0, T]$$

$$C_T = \{a \leq x \leq b, t = 0\} \cup \{a, 0 \leq t \leq T\} \cup \{b, 0 \leq t \leq T\}$$

Theorem 1.1: Maximum principle

If $u \in C(\overline{R_T}) \cap C^2(R_T)$ is a solution of the diffusion equation, then $u(x, t) \leq \max_{C_T} \{u\}$ for all $(x, t) \in R_T, T > 0$. Here C_T is called the parabolic boundary of R_T .

Remark:

1. We can replace $u_t - ku_{xx} = 0$ with $u_t - ku_{xx} \leq 0$.
2. A stronger version of the theorem exists which says that $u(x, t) < \max_{C_T} \{u\}$ unless u is constant.
3. Same result applies to the minimum of u by replacing u with $-u$. However, in this case, (1) doesn't apply. Now we need $u_t - ku_{xx} \geq 0$.

Here are some intuitions. Consider a rod lying on $[a, b]$ with initial non-constant temperature $T_0(x)$. Then as time goes, only blue T is possible, not red T .

Proof:

Let $M = \max_{C_T} u$. Note that M exists since u is continuous on C_T , and C_T is a closed boundary. We need to show that $u \leq M$ on $\overline{R_T}$.

Let

$$v(x, t) = u(x, t) + \epsilon x^2, \quad \epsilon > 0$$

Let $r = \max\{|a|, |b|\}$. Then $v(x, t) \leq M + \epsilon r^2$ on C_T . Now we prove that $v \leq M + \epsilon r^2$ on R_T .

On R_T , we have

$$u = v - \epsilon x^2 \leq M + \epsilon(r^2 - x^2)$$

Now if we take the derivative,

$$v_t - kv_{xx} = u_t - ku_{xx} - 2k\epsilon = -2k\epsilon < 0 \quad (*)$$

- (i) Suppose $v(x, t)$ has a maximum at an interior point (x_0, t_0) , i.e., $(x_0, t_0) \in (a, b) \times (0, T)$. Then

$v_t(x_0, t_0) = 0$. Moreover, $v_{xx}(x_0, t_0) \leq 0$. Then

$$v_t(x_0, t_0) - kv_{xx}(x_0, t_0) = -kv_{xx}(x_0, t_0) \geq 0$$

contradicting (*), thus there are no interior max.

(ii) Suppose $v(x, t)$ has a maximum at an interior point of the upper boundary. $v_t(x_0, T) \geq 0$. Then

$$v_t(x_0, T) - kv_{xx}(x_0, T) \geq 0$$

contradicting (*), thus there are no maximum along the upper boundary.

But v is continuous on $\overline{R_T}$, thus it has a maximum value which we now know must occur on C_T . Hence $v \leq M + \epsilon r^2$ on $\overline{R_T}$. Letting $\epsilon \rightarrow 0$, we have $u \leq M$ on R_T . \square

1.4 Uniqueness of the Dirichlet Problem

$$\begin{aligned} u_t - ku_{xx} &= f(x, t) & a < x < b, 0 < t < \infty \\ u(x, 0) &= \phi(x) \\ u(a, t) &= g(t) \\ u(b, t) &= h(t) \end{aligned} \tag{1.1}$$

Theorem 1.2

The solution of (1.1) is unique.

Proof:

Suppose there are two solutions $u_1(x, t)$ and $u_2(x, t)$. Let $w(x, t) = u_1 - u_2$. Now we calculate

$$\begin{aligned} w_t - kw_{xx} &= (u_{1t} - ku_{1xx}) - (u_{2t} - u_{2xx}) = f - f = 0 \\ w(x, 0) &= u_1(x, 0) - u_2(x, 0) = \phi - \phi = 0 \\ w(a, t) &= w(b, t) = 0 \end{aligned}$$

By maximum principle, we have $w \leq 0$ on the boundary, and by minimum principle, $w \geq 0$, since $\max_{C_T} \{w\} = \min_{C_T} \{w\} = 0$. Then we conclude that $w \equiv 0$. \square

Now we present a second proof using energy method:

Proof:

Given $w_t - kw_{xx} = 0$, multiply both sides by w :

$$0 = ww_t - kw_{xx} = \frac{\partial}{\partial t} \left(\frac{1}{2} w^2 \right) - k \frac{\partial}{\partial x} (ww_x) + kw_x^2$$

If we integrate both sides,

$$\frac{d}{dt} \int_a^b \frac{1}{2} w^2 dx = k \int_a^b (ww_x)_x dx - k \int_a^b w_x^2 dx = kww_x \Big|_a^b - k \int_a^b w_x^2 dx$$

Thus

$$\frac{d}{dt} \int_a^b \frac{1}{2} w^2 dx = -k \int_a^b w_x^2 dx$$

Then

$$\int_a^b \frac{1}{2} w^2 dx = 0 \quad \text{for all the time}$$

Then $w \equiv 0$ on $a \leq x \leq b, 0 \leq t \leq T$. \square

Now let's examine stability. Consider

$$\begin{aligned} u_t - ku_{xx} &= 0 \\ u(a, t) &= u(b, t) = 0 \end{aligned}$$

and let $u_j(x, t)$ be the solution for $u(x, 0) = \phi_j(x)$ for $j = 1, 2$.

Let $w = u_1 - u_2$. Proceeding as before (energy method) we have

$$\int_a^b (u_1 - u_2)^2 dx \leq \int_a^b (\phi_1 - \phi_2)^2 dx$$

This tells us $\|u_1 - u_2\|_2 \rightarrow 0$ as $\|\phi_1 - \phi_2\|_2 \rightarrow 0$. This is called **stability in the square integrable sense**.

Alternatively, by maximum principle,

$$\max |u_1 - u_2| \leq \max |\phi_1 - \phi_2|$$

using maximum & minimum principle, i.e.,

$$\begin{aligned} \max\{u_1 - u_2\} &\leq \max\{\phi_1 - \phi_2\} \\ \min\{u_1 - u_2\} &\geq \min\{\phi_1 - \phi_2\} \end{aligned}$$

This is called **stability in the uniform sense**.

1.5 Diffusion on the Whole Line

Consider the initial value problem

$$u_t - ku_{xx} = 0 \quad \text{on } -\infty < x < \infty, \quad 0 < t < \infty \quad (1.2)$$

$$u(x, 0) = \phi(x) \quad (1.3)$$

If $s(x, t)$ is a solution of (1.2), then so is

$$u(x, t) = \int_{-\infty}^{\infty} s(x - y, t) g(y) dy \quad (1.4)$$

for any function $g(y)$. We can find u_t, u_x, u_{xx} and take it into (1.2):

$$u_t - ku_{xx} = \int_{-\infty}^{\infty} [s_t(x - y, t) - ks_{xx}(x - y, t)] g(y) dy = 0$$

So we now find a solution of (1.2) with the property that $s(x, 0) = \delta(x)$, i.e., solve

$$\begin{aligned} s_t - ks_{xx} &= 0 \\ s(x, 0) &= \delta(x) \end{aligned}$$

To do this, consider the problem:

$$\begin{aligned} v_t - kv_{xx} &= 0 \\ v(x, 0) &= v_0 H(x) \end{aligned} \quad (1.5)$$

$H = \text{Heaviside function}$

v_0 carries the dimension of v , thus $H(x)$ is dimensionless.

Similarity solution of (1.5)

Let $Q = \frac{v}{v_0}$ which is dimensionless, then the original problem gets transformed to

$$\begin{aligned} Q_t &= kQ_{xx} \\ Q(x, 0) &= H(x) \end{aligned}$$

The solution can only be a function of x, t and k : $Q = F(x, t, k)$. Then we can apply dimensionless analysis. This means Q can only depend on dimensionless combinations of x, t and k . We have

$$\begin{aligned} [x] &= L \\ [t] &= T \\ [k] &= \frac{L^2}{T} \end{aligned}$$

Then

$$[x^a t^b k^c] = L^a T^b \frac{L^{2c}}{T^c} \implies b = c, 2c = -a$$

This tells us

$$Q = f(\theta) \quad \text{where } \theta = \frac{x}{\sqrt{kt}}$$

By chain rule, we have

$$\begin{aligned} Q_t &= f'(\theta) \cdot \theta_t = -\frac{1}{2} \frac{\theta}{t} f'(\theta) \\ Q_x &= f'(\theta) \cdot \theta_x = \frac{1}{\sqrt{kt}} f'(\theta) \\ Q_{xx} &= \frac{1}{kt} f''(\theta) \end{aligned}$$

Then

$$\begin{aligned} Q_t - kQ_{xx} &= -\frac{\theta}{2t} f' - \frac{k}{kt} f'' = 0 \\ f''(\theta) &= -\frac{1}{2} \theta f'(\theta) \\ f'(\theta) &= A e^{-\frac{\theta^2}{4}} \\ f(\theta) &= A \int_{-\infty}^{\theta} e^{-s^2/4} ds + C \end{aligned}$$

As $x \rightarrow +\infty, \theta \rightarrow +\infty$, and $Q(x, t) = f(\theta) \rightarrow 1$. Then $\lim_{\theta \rightarrow +\infty} f(\theta) = 1$.

As $x \rightarrow -\infty, \theta \rightarrow -\infty$ and $Q(x, t) = f(\theta) \rightarrow 0$, $\lim_{\theta \rightarrow -\infty} f(\theta) = 0$.

Therefore, C must be 0, and $A \int_{-\infty}^{\infty} e^{-s^2/4} ds = 1$. Using the change of variable $\eta = \frac{s}{2}$:

$$\int_{-\infty}^{\theta} e^{-s^2/4} ds = 2 \int_{-\infty}^{\theta/2} e^{-\eta^2} d\eta = 2 \int_{-\infty}^{x/\sqrt{4kt}} e^{-\eta^2} d\eta$$

So if we take $\theta = \frac{x}{\sqrt{4kt}}$ at the beginning, we get $\tilde{A} = 2A$ and

$$\tilde{A} \int_{-\infty}^{\infty} e^{-s^2} ds = 1 \implies \tilde{A} = \frac{1}{\sqrt{\pi}}$$

Thus we get

$$Q = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{x/\sqrt{4kt}} e^{-s^2} ds$$

Note that for $x > 0$, as $t \rightarrow 0^+$, $\frac{x}{\sqrt{4kt}} \rightarrow +\infty$ and $Q(x, t) \rightarrow \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} e^{-s^2} ds = 1$.

And for $x < 0$ as $t \rightarrow 0^+$, $Q \rightarrow 0$. The reason for the name “similarity solution” is because the curve is being stretched over time.

$s(x, t)$ has many names: source function (not a great name), Green’s function, fundamental solution, propagator of the diffusion equation, diffusion kernel...

Consider a diffusion equation with initial condition

$$\begin{aligned} u_t + ku_{xx} &= 0 \\ u(x, 0) &= \delta(x) \end{aligned}$$

The solution is Gaussian

$$u = \frac{1}{\sqrt{4\pi kt}} e^{-\frac{x^2}{4kt}}$$

For any $t > 0$, u is non-zero. It gets instantaneously non-zero everywhere.

Reflections and Sources

2.1 Diffusion on the Half-Line

We will start with diffusion on the half line Dirichlet problem.

$$\begin{aligned} v_t - kv_{xx} &= 0 & 0 < x < \infty, 0 < t < \infty \\ v(x, 0) &= \phi(x) \\ v(0, t) &= 0 \quad \text{for } t > 0 \end{aligned}$$

Let

$$\phi_{odd} = \begin{cases} \phi(x) & x > 0 \\ -\phi(-x) & x < 0 \end{cases}$$

and solve

$$\begin{aligned} u_t + ku_{xx} &= 0 & \text{on } -\infty < x < \infty \\ u(x, 0) &= \phi_{odd}(x) \end{aligned}$$

Then $v(x, t)$ is restriction of u to $x > 0$. From an earlier result

$$u(x, t) = \int_{-\infty}^{\infty} s(x - y, t) \phi_{odd}(y) \, dy$$

where

$$s(x, t) = \frac{e^{-\frac{x^2}{4kt}}}{\sqrt{4\pi kt}}$$

Claim From the property of s and ϕ_{odd} , we can show that $u(x, t)$ is an odd function of x . Thus $u(0, t) = 0$.

Now we see that

$$\begin{aligned} u(x, t) &= \int_{-\infty}^0 s(x - y, t) [-\phi(-y)] \, dy + \int_0^{\infty} s(x - y, t) \phi(y) \, dy \\ &= \int_{-\infty}^0 s(x + y, t) \phi(y) \, dy + \int_0^{\infty} s(x - y, t) \phi(y) \, dy & \text{let } y = -y \\ &= \frac{1}{\sqrt{4\pi kt}} \int_0^{\infty} \left[e^{-\frac{(x-y)^2}{4kt}} - e^{-\frac{(x+y)^2}{4kt}} \right] \phi(y) \, dy \end{aligned} \tag{2.1}$$

Example:

$$\begin{aligned} v_t - kv_{xx} &= 0 & 0 < x < \infty \\ v(x, 0) &= 1 & x > 0 \\ v(0, t) &= 0 \end{aligned}$$

Then $\phi_{odd} = -1 + 2H(x)$.

Recall the solution of

$$\begin{aligned} u_t - ku_{xx} &= 0 \\ u(x, 0) &= H(x) \end{aligned} \tag{2.2}$$

is

$$u(x, t) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{x/\sqrt{4k\pi}} e^{-s^2} ds$$

Let $u(x, t) = -1 + 2q(x, t)$. Then $q(x)$ is the solution to (2.2). Hence we have

$$u = -1 + \frac{2}{\sqrt{\pi}} \int_{-\infty}^{x/\sqrt{4k\pi t}} e^{-s^2} ds = \operatorname{erf}\left(\frac{x}{\sqrt{4kt}}\right)$$

Another way to solve is to use (2.1).

Consider Neumann Boundary condition ($0 < x < \infty$):

$$\begin{aligned} u_t - ku_{xx} &= 0 \\ u(x, 0) &= \phi(x) \\ u_x(0, t) &= 0 \end{aligned}$$

We can let

$$\phi_{even} = \begin{cases} \phi(x) & x > 0 \\ \phi(-x) & x < 0 \end{cases}$$

and solve

$$\begin{aligned} u_t - ku_{xx} &= 0 \\ u(x, 0) &= \phi_{even} \end{aligned}$$

With some algebra, we get

$$u = \frac{1}{\sqrt{4\pi kt}} \int_0^\infty \left[e^{-\frac{(x-y)^2}{4kt}} + e^{-\frac{(x+y)^2}{4kt}} \right] \phi(y) dy$$

2.2 Reflections of Waves

Dirichlet Problem on the half line

$$\begin{aligned} v_{tt} - c^2 v_{xx} &= 0 & 0 < x < \infty \\ v(x, 0) &= \phi(x) \\ v_t(x, 0) &= \psi(x) \\ v(0, t) &= 0 \end{aligned}$$

The idea is $u(-x, t) = -u(x, t)$, then $u = 0$ at $x = 0$. So consider an odd reflection about $x = 0$:

$$\phi_{odd} = \begin{cases} \phi(x) & x > 0 \\ -\phi(-x) & x < 0 \end{cases} \quad \psi_{odd} = \begin{cases} \psi(x) & x > 0 \\ -\psi(-x) & x < 0 \end{cases}$$

We know that the solution of $(-\infty < x < \infty)$

$$\begin{aligned} u_{tt} - c^2 u_{xx} &= 0 \\ u(x, 0) &= \phi_{\text{odd}}(x) \\ u_t(x, 0) &= \psi_{\text{odd}}(x) \end{aligned}$$

is

$$u(x, t) = \frac{1}{2} [\phi_{\text{odd}}(x + ct) + \phi_{\text{odd}}(x - ct)] + \frac{1}{2c} \int_{x-ct}^{x+ct} \psi_{\text{odd}}(y) \, dy$$

Note that $(t > 0)$

$$u(0, t) = \frac{1}{2} [\phi_{\text{odd}}(ct) + \phi_{\text{odd}}(-ct)] + \frac{1}{2c} \int_{-ct}^{ct} \psi_{\text{odd}}(y) \, dy = 0$$

which satisfies the initial condition.

3 cases of the solution

(a) $x > c|t|$, then $x + ct > 0, x - ct > 0$, then the solution $(t > 0)$ becomes

$$u(x, t) = \frac{1}{2} [\phi(x + ct) + \phi(x - ct)] + \frac{1}{2c} \int_{x-ct}^{x+ct} \psi(y) \, dy$$

(b) Consider $0 < x < ct, t > 0$, we have $x - ct < 0, x + ct > 0$. Then

$$\begin{aligned} \phi_{\text{odd}}(x - ct) &= -\phi(-x + ct) \\ \phi_{\text{odd}}(x + ct) &= \phi(x + ct) \end{aligned}$$

and

$$\begin{aligned} \int_{x-ct}^{x+ct} \psi_{\text{odd}}(y) \, dy &= \int_{x-ct}^0 [-\psi(-y)] \, dy + \int_0^{x+ct} \psi(y) \, dy \\ &= -\int_0^{-x+ct} \psi(y) \, dy + \int_0^{x+ct} \psi(y) \, dy \\ &= \int_{-(x-ct)}^{x+ct} \psi(y) \, dy \end{aligned}$$

Therefore

$$u = \frac{1}{2} [\phi(x + ct) - \phi(-(x - ct))] + \frac{1}{2c} \int_{-(x-ct)}^{x+ct} \psi(y) \, dy$$

2.3 Diffusion with a Source

$$\begin{aligned} u_t - ku_{xx} &= f(x, t) & -\infty < x < \infty \\ u(x, 0) &= \phi(x) & 0 < t < \infty \end{aligned}$$

We can solve

$$\begin{aligned} u_t - ku_{xx} &= f(x, t) \\ u(x, 0) &= 0 \end{aligned} \tag{2.3}$$

and

$$\begin{aligned} u_t - ku_{xx} &= 0 \\ u(x, 0) &= \phi(x) \end{aligned}$$

and sum to get the solution.

Duhamel's Principle for first order linear ODEs

The solution of

$$\begin{aligned} y' + ay &= F(t) & t > 0, \quad a \text{ constant} \\ y(0) &= 0 \end{aligned}$$

is given by

$$y(t) = \int_0^t w(t-s; s) \, ds$$

where $w(t; s)$ is the solution of

$$\begin{aligned} w_t(t; s) + aw(t; s) &= 0 \\ w(0; s) &= F(s) \end{aligned}$$

Proof:

$$\frac{d}{dt}(e^{at}y) = e^{at}F(t) = e^{at}y = \int_0^t e^{as}F(s) \, ds$$

Then

$$y = \int_0^t e^{a(s-t)}F(s) \, ds$$

Using initial condition $y(0) = 0$ and $w(t, s) = F(s)e^{-at}$,

$$w(t-s; s) = F(s)e^{a(s-t)}$$

Thus

$$y(t) = \int_0^t w(t-s; s) \, ds$$

□

We are now to guess that this works for the diffusion equation, i.e., guess the solution of (2.3) is

$$u(x, t) = \int_0^t w(x, t-s; s) \, ds$$

where $w(x, t; s)$ is the solution of

$$\begin{aligned} w_t - kw_{xx} &= 0 \\ w(x, 0; s) &= f(x, s) \end{aligned}$$

From previous work

$$w = \int_{-\infty}^{\infty} s(x-y, t)f(y, s) \, dy$$

Then

$$u = \int_0^t \int_{-\infty}^{\infty} S(x-y, t)f(y, s) \, dy \, ds \quad (2.4)$$

We need to verify that this is indeed the solution

$$\begin{aligned} u_t &= \int_{-\infty}^{\infty} s(x-y, 0)f(y, t) \, dy + \int_0^t \int_{-\infty}^{\infty} s_t(x-y, t-s)f(y, s) \, dy \, ds \\ &= f(x, y) + \int_0^t \int_{-\infty}^{\infty} s_t(x-y, t-s)f(y, s) \, dy \, ds \end{aligned}$$

Next

$$u_{xx} = \int_0^t \int_{-\infty}^{\infty} s_{xx}(x-y, t-s)f(y, s) \, dy \, ds$$

Then we see that $u_t - ku_{xx} = f(x, t)$ and $u(x, 0) = 0$.

Therefore (2.4) is a solution of (2.3). Then add $\int_{-\infty}^{\infty} S(x-y, t)\phi(y) \, dy$ to add IC $u(x, 0) = \phi(x)$.

2.4 Source on a half line

$$\begin{aligned} u_t - ku_{xx} &= f(x, t) & 0 < x < \infty, \quad 0 < t < \infty \\ u(x, 0) &= \phi(x) \\ u(0, t) &= h(t) \end{aligned}$$

where $h(t)$ is the source on the boundary.

Let $v(x, t) = u(x, t) - h(t)$, then

$$\begin{aligned} v_t - kv_{xx} &= u_t - ku_{xx} - h'(t) = f(x, t) - h'(t) \\ v(x, 0) &= \phi(x) - h(0) = \tilde{\phi}(x) \\ v(0, t) &= 0 \end{aligned}$$

Then we can use odd extension and solve

$$\begin{aligned} v_t - kv_{xx} &= \tilde{f}(x, t) := f_{\text{odd}} - h'(t) \\ v(x, 0) &= \tilde{\phi}_{\text{odd}} \end{aligned}$$

Use previous solution and restrict to the positive x -axis to get $v(x, t)$ and then $u(x, t) = v(x, t) + h'(t)$.

Theorem 2.1

Let $\phi(x)$ be a bounded continuous function on $-\infty < x < \infty$. Then

$$u(x, t) = \int_{-\infty}^{\infty} S(x - y, t) \phi(y) \, dy \quad (2.5)$$

where

$$S(x, t) = \frac{1}{\sqrt{4\pi kt}} e^{-\frac{x^2}{4kt}}$$

defines an C^∞ solution of

$$\begin{aligned} u_t - ku_{xx} &= 0 & -\infty < x < \infty, \quad t > 0 \\ u(x, 0) &= \phi(x) \end{aligned}$$

Proof:

Sub $S(x, t)$ in, we get

$$u(x, t) = \frac{1}{\sqrt{4\pi kt}} \int_{-\infty}^{\infty} e^{-\frac{(x-y)^2}{4kt}} \phi(y) \, dy$$

We now introduce the change of variable,

$$\frac{x - y}{\sqrt{kt}} = p$$

then

$$y = x - \sqrt{kt}p, \quad dy = -\sqrt{kt} \, dp$$

Then

$$\begin{aligned} u(x, y) &= \frac{1}{\sqrt{4\pi kt}} \int_{-\infty}^{\infty} e^{-p^2/4} \phi(x - \sqrt{kt}p) (-\sqrt{kt} \, dp) \\ &= \frac{1}{\sqrt{4\pi}} \int_{-\infty}^{\infty} e^{-p^2/4} \phi(x - \sqrt{kt}p) \, dp \end{aligned}$$

Thus

$$\begin{aligned} |u(x, t)| &\leq \frac{1}{\sqrt{4\pi}} \int_{-\infty}^{\infty} e^{-p^2/4} |\phi(x - \sqrt{kt}p)| \, dp \\ &= \frac{\max |\phi|}{\sqrt{4\pi}} \int_{-\infty}^{\infty} e^{-p^2/4} \, dp \\ &= \max |\phi| \end{aligned}$$

Thus (2.5) integral converges absolutely and uniformly.

Formally

$$u_x(x, t) = \int_{-\infty}^{\infty} \frac{\partial}{\partial x} S(x - y, t) \phi(y) \, dy$$

and these two are equal of the integral converges absolutely.

Consider

$$\begin{aligned} I(x, t) &= \int_{-\infty}^{\infty} S_x(x - y, t) \phi(y) \, dy \\ &= \frac{1}{\sqrt{4\pi kt}} \int_{-\infty}^{\infty} \left[-\frac{(x - y)}{2kt} e^{-\frac{(x - y)^2}{4kt}} \right] \phi(y) \, dy \\ &= \frac{1}{\sqrt{4\pi kt}} \int_{-\infty}^{\infty} \frac{-\sqrt{kt}p}{2kt} e^{-p^2/4} \phi(x - \sqrt{kt}p) \sqrt{kt} \, dp \\ &= -\frac{1}{4\sqrt{\pi k}} \frac{1}{\sqrt{t}} \phi(x - \sqrt{kt}p) \, dp \end{aligned}$$

Therefore, for C constant

$$|I| \leq \frac{C \max |\phi|}{\sqrt{t}} \int_{-\infty}^{\infty} |p| e^{-p^2/4} \, dp$$

converges.

Therefore

$$\int_{-\infty}^{\infty} S_x(x - y, t) \phi(y) \, dy$$

converges absolutely and hence is equal to u_x . Similarly all $\frac{\partial^{m+n} u}{\partial t^m \partial x^n}$ exist because they will all be the sum of integrals of the form $A \int_{-\infty}^{\infty} |p^j| e^{-p^2/4} \, dp$ which converges for all j .

Hence

$$u_t - ku_{xx} = \int_{-\infty}^{\infty} [S_t(x - y, t) - kS_{xx}(x - y, t)] \phi(y) \, dy = 0$$

since S is a solution of the diffusion equation.

Now we check the initial condition. Since formally $S(x, t)$ does not exist at $t = 0$ by “the IC is satisfied” we mean $\lim_{t \rightarrow 0^+} u(x, t) = \phi(x)$. Now

$$u(x, t) - \phi(x) = \int_{-\infty}^{\infty} s(x - y, t) [\phi(y) - \phi(x)] \, dy$$

Using $y = x - \sqrt{kt}p$ as before

$$u(x, t) - \phi(x) = \frac{1}{\sqrt{4\pi}} \int_{-\infty}^{\infty} e^{-p^2/4} (\phi(x - \sqrt{kt}p) - \phi(x)) \, dp$$

If we fix x , $\phi(x)$ is continuous at x , so for $\epsilon > 0$, there exists $\delta > 0$ such that

$$|y - x| < \delta \implies |\phi(x + \delta) - \phi(x)| < \frac{\epsilon}{2}$$

$$\begin{aligned}
u(x,t) - \phi(x) &= \frac{1}{\sqrt{4\pi}} \int_{-\infty}^{\infty} e^{-p^2/4} \left(\phi(x - \sqrt{kt}p) - \phi(x) \right) dp \\
&= \frac{1}{\sqrt{4\pi}} \int_{|p| < \frac{\delta}{\sqrt{kt}}} e^{-p^2/4} \underbrace{\left(\phi(x - \sqrt{kt}p) - \phi(x) \right)}_{\substack{\text{abs value } < \epsilon/2 \\ \text{on } |p| < \delta/\sqrt{kt}}} dp + \frac{1}{\sqrt{4\pi}} \int_{|p| > \frac{\delta}{\sqrt{kt}}} \dots dp \\
&\leq \frac{\epsilon}{2} + \frac{2 \max |\phi|}{\sqrt{4\pi}} \int_{|p| > \frac{\delta}{\sqrt{kt}}} e^{-p^2/4} dp
\end{aligned}$$
